

Transit

Transit is the purchasing of Internet access by a network operator from another network operator (known as their upstream provider).

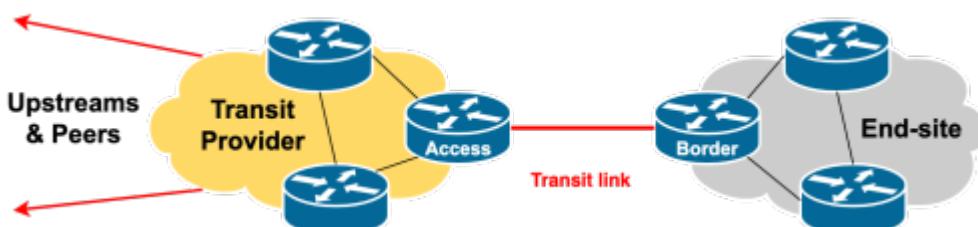

The vast majority of transit attracts traffic charges. Charges are normally levied on traffic levels (typically measured in US\$ per Mbps per month). Charges vary from region to region, and the quantity committed to. For example, committing to 100Mbps will attract a much higher charge per Mbps than committing to 1Gbps would.

Some locations charge based on outright volume (usually of downloads, but some combine both downloads and uploads), which can make Internet access very expensive. This method is reminiscent of legacy telephony plans which permit so many calls per month, or mobile data plans allowing the user so many call minutes and/or Gbytes of download per month.

The choice of a transit provider is beyond the scope of the Peering Toolbox; however typical considerations include (in no particular order):

- cost of the link (physical as well as traffic)
- reliability of the link and of the transit provider
- service quality provided by the transit provider
- latency to destinations that are important for the end-site operator
- bandwidth available through transit provider network
- the transit provider's diversity of peering and transit arrangements

All of these considerations are important - it's not just about cost, even though cost minimisation is desirable!
